Appendix B-1: EMME Output
Appendix B-2: Reference and Simulated Volumes
Appendix B-3: VISSIM Output - Intersection Operations
Appendix B-4: VISSIM Output - Travel Times

## 1. INTRODUCTION

The Downtown Transportation Study was commissioned by the City of Regina to assess transportation related needs and opportunities in the area between $13^{\text {th }}$ Avenue and Saskatchewan Drive, and between Broad Street and Albert Street. The Study has been divided into two Phases, with Phase 1 focusing on the $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue corridors. This report follows the Downtown Transportation Study Phase 1 Existing Conditions Report, May 2012. The Existing Conditions Report detailed the development of a VISSIM micro-simulation model of the $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue corridors, and provided an overview of traffic and transit operations along the corridors.

### 1.1 Purpose of Report

This report provides the evaluation of options for $12^{\text {th }}$ Avenue at City Square Plaza. Three overall alternatives were defined in the study scope: opening the $12^{\text {th }}$ Avenue Plaza to traffic one-way eastbound, one-way westbound, and two-way. Potential sub-alternatives include time-of-day or seasonal openings and alternative lane configurations. This report provides an operational assessment of these three alternatives, plus a fourth alternative. As detailed in the primary Phase 1 report, the emerging preferred alternative is to open the Plaza to traffic one-way westbound, with limited accessibility provided by limiting access to the Plaza to Scarth Street from the south or to Cornwall Street from the north.

Additionally, select items from the list of potential network improvements are chosen and implemented on the preferred alternative. This report provides the details regarding what was changed, and the results of the changes.

### 1.2 Network Alternatives

Development and validation of the base model was detailed in the Existing Conditions Report. The base model represents PM peak hour, with $12^{\text {th }}$ Avenue closed between Lorne Street and Scarth Street, which is the stretch adjacent to City Square Plaza. This decision was based on the fact that the closure reflected the state of current operations at the plaza, and that PM peak hour was observed to have the highest auto volumes and congestion levels in the study area.

In Exhibit 1-1, the map of Downtown Regina is shown with three boundaries. The area enclosed in the red boundary represents the stretch of $12^{\text {th }}$ Avenue that is closed under current operations, but is subject to alternative operations. The area enclosed in the dark blue boundary represents the study area for Phase 1 of the project. The area enclosed by the light blue boundary represents the study area for Phase 2 of the project.

Exhibit 1-1: Regina Downtown Transportation Study Area

Given the base model with the City Square Plaza closed to traffic, the main network alternatives reviewed in this report are:

- The one-way eastbound alternative would allow continuous eastbound movement along $12^{\text {th }}$ Avenue. Based on a review of potential traffic operations in the plaza, the eastbound movement would be restricted to a single lane at Lorne Street, with a posted speed in the Plaza of $20 \mathrm{~km} / \mathrm{h}$. Under this alternative Cornwall Street is extended to connect $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue, operating as a two-way north-south street with one lane per direction. At $12^{\text {th }}$ Avenue and Cornwall Street, eastbound cars can either continue eastbound through or take a left turn into Cornwall Street. Southbound cars must take a left turn to merge into $12^{\text {th }}$ Avenue eastbound. $12^{\text {th }}$ Avenue has priority in the intersection, and southbound Cornwall traffic must stop and yield to $12^{\text {th }}$ Avenue traffic. At $12^{\text {th }}$ Avenue and Scarth Street, eastbound cars must continue eastbound. Northbound cars on Scarth Street must take northbound right.
- The one-way westbound alternative would provide for continuous movement along $12^{\text {th }}$ Avenue from Broad Street to Albert Street and beyond. Again, the westbound movement is restricted to a single lane, and the designated speed is $20 \mathrm{~km} / \mathrm{h}$. Cornwall Street is extended to connect $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue, operating as a two-way
north-south street with one lane per direction. At $12^{\text {th }}$ Avenue and Cornwall Street, westbound cars can either continue westbound through or take a right turn into Cornwall Street. Southbound cars must take a right turn to merge into $12^{\text {th }}$ Avenue westbound. $12^{\text {th }}$ Avenue has priority in the intersection, and southbound Cornwall traffic must stop and yield to $12^{\text {th }}$ Avenue traffic. At $12^{\text {th }}$ Avenue and Scarth Street, the northbound left turn is enabled, allowing traffic from Scarth Street to merge into $12^{\text {th }}$ Avenue westbound as well as turn east. In this configuration, the easternmost part of the Plaza is two-way.
- The two-way alternative allows both eastbound and westbound through movements of cars on $12^{\text {th }}$ Avenue between Lorne Street and Hamilton street, providing a continuous movement on $12^{\text {th }}$ Avenue in both directions. Traffic is limited to a single lane in each direction, and the designated speed is $20 \mathrm{~km} / \mathrm{h}$. Cornwall Street is again extended to connect $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue, operating as a two-way north-south street with one lane per direction. At $12^{\text {th }}$ Avenue and Cornwall Street, all available movements are enabled: EBL, EBT, WBT, WBR, SBL, and SBR. At $12^{\text {th }}$ Avenue and Scarth Street, northbound left turn is enabled, allowing traffic from Scarth Street to merge into $12^{\text {th }}$ Avenue westbound.
- The fourth alternative, following from the evaluation and traffic planning for the Plaza is a restricted one-way westbound configuration. This configuration is based on the one-way westbound alternative but imposes two additional limitations on the network:
o At $12^{\text {th }}$ Avenue and Scarth Street, there is no westbound access. Westbound vehicles must exit into the alleyway or take a u-turn to proceed in the eastbound direction. Northbound left is still enabled, and it is the only access to $12^{\text {th }}$ Avenue westbound from Scarth Street to Cornwall Street.
o The intersection of $12^{\text {th }}$ Avenue and Cornwall Street operates as a forced right-in right-out. Westbound traffic on $12^{\text {th }}$ Avenue must take right turn into Cornwall Street northbound, and southbound traffic on Cornwall Street must take right turn into $12^{\text {th }}$ Avenue westbound.
- The one-way westbound configuration with these additional restrictions provides the benefit of limiting westbound traffic in the Plaza to local traffic only. No through traffic from Hamilton Street or east of Hamilton Street can travel into the Plaza and use it as a through-route.

## 2. MODEL DEVELOPMENT

Development of VISSIM models, for detailed evaluation of alternatives, followed a process of demand definition, network coding, and model runs. Demand definition was based on application of the City's regional demand model, and adjustments for routing, balancing, and logic checks. Network coding followed the standards set out in the Existing Conditions Report. Model runs and calibration were undertaken to ensure that each alternative modelled the anticipated traffic levels and that operations were correct for the scenario.

### 2.1 EMME Models

All alternatives were assigned a separate scenario in the City's regional demand model, using the base 2009 matrix for assignment. The base matrix is the closest in terms of demand to the current
year, and network edits were made to reflect each scenario. A pivot-based approach was used, where the EMME model was used to assess vehicle routing and diversion potential. This approach cancels out some of the inherent model error for a local area transportation study of collector roads, as the absolute forecasts from the model are not used, only relative differences between scenarios are used to adjust traffic flows. Exhibit 2-1 provides EMME forecasts (unadjusted) from the City's demand model.

Exhibit 2-1: PM Peak EMME Assigned Volumes, Westbound and Eastbound

The large trends in EMME models are as follows:

- On $11^{\text {th }}$ Avenue, eastbound and westbound volumes west of Smith Street and east of Hamilton Street do not change significantly from one alternative to another.
- On $11^{\text {th }}$ Avenue, eastbound and westbound volumes between Smith Street and Hamilton Street change significantly from one alternative to another. Eastbound and westbound volumes for one-way alternatives are about 150-200 vehicles less than the base model. Eastbound and westbound volumes for two-way alternative are about 200-350 vehicles less than the base model.
- On $12^{\text {th }}$ Avenue, volumes are adjusted accordingly to the $12^{\text {th }}$ Avenue operations at City Square Plaza.
- For north-south streets, the volumes are generally within the same vicinity between all models, with the exception of Lorne Street and Cornwall Street. For Lorne Street, volumes are 50-70\% higher for the one-way westbound alternative and the two-way alternative compare to the base model. In the EMME base model, Cornwall Street is closed for the base model (cars enter the Cornwall parkade directly using a centroid connector), and it is open for the alternatives.

Due to the fact that the alternative featuring one-way westbound preferred was developed largely based on the one-way westbound alternative, a separate EMME analysis was not conducted for that particular alternative.

Full maps of the alternatives in EMME are available in Appendix B-1.

### 2.2 Synchro Models

For each alternative, including the one-way westbound with limitations, a Synchro model was developed. The Synchro model provides a simple method of calculating service levels at intersections and in comparing those service levels against the VISSIM model. The intersection turning movement volumes and configurations, signal timings and signage, and desired speeds are identical between the Synchro model and the VISSIM model. Transit vehicles and routes, parking manoeuvres, and pedestrian-vehicle conflicts in the link (not at intersections) are not modelled in Synchro.

Exhibit 2-3 through to Exhibit 2-7 illustrate the Synchro models and turning movement forecasts. Further details on establishing the traffic volumes are provided in Section 2.4 of this report. The Synchro-generated output reports provided in the appendix contain evaluations for each intersection turning movement's delay, level of service (LOS), and queue lengths.

Exhibit 2-3: Downtown Regina: Synchro Model, PM Base Closed

Exhibit 2-4: Downtown Regina: Synchro Model, PM One-Way Eastbound

Exhibit 2-5: Downtown Regina: Synchro Model, PM One-Way Westbound

Exhibit 2-6: Downtown Regina: Synchro Model, PM Two-Way

Exhibit 2-7: Downtown Regina: Synchro Model, PM One-Way Westbound Preferred

### 2.3 VISSIM Models

A VISSIM model was developed for each alternative. The intersection turning movement volumes and configurations, signal timings and signage, and desired speeds are identical between the Synchro model and the VISSIM model. Transit routes and vehicles are modelled fully in VISSIM. For details regarding transit in VISSIM, see section 1.

Exhibit 2-8: Downtown Regina: VISSIM Model, PM Base Closed Network

Exhibit 2-9: $12^{\text {th }}$ Avenue at City Square Plaza, One-Way Eastbound

Exhibit 2-10: $12^{\text {th }}$ Avenue at City Square Plaza, One-Way Westbound

Exhibit 2-11: $12^{\text {th }}$ Avenue at City Square Plaza, Two-Way

Exhibit 2-12: $12^{\text {th }}$ Avenue at City Square Plaza, One-Way Westbound Preferred

Vehicle speeds are controlled with desired speed decision points and reduced speed areas. The following desired speed categories are set for various movements in the model, in order to best reflect realistic driving behaviour. Desired speed decisions and reduced speed areas are the same between all models.

Exhibit 2-13: Model Desired Speeds

| Link | Desired Speed Category | Speed Distribution |
| :--- | :---: | :---: |
| $12^{\text {th }}$ Avenue at City Square Plaza | $20 \mathrm{~km} / \mathrm{h}$ | $20.0 \mathrm{~km} / \mathrm{h}-25.0 \mathrm{~km} / \mathrm{h}$ |
| All left turn movements | $15 \mathrm{~km} / \mathrm{h}$ | $15.0 \mathrm{~km} / \mathrm{h}-20.0 \mathrm{~km} / \mathrm{h}$ |
| All right turn movements | $12 \mathrm{~km} / \mathrm{h}$ | $12.0 \mathrm{~km} / \mathrm{h}-15.0 \mathrm{~km} / \mathrm{h}$ |
| Everywhere else | $50 \mathrm{~km} / \mathrm{h}$ | $48.0 \mathrm{~km} / \mathrm{h}-58.0 \mathrm{~km} / \mathrm{h}$ |

Priority Rules and conflict areas were defined in various places of the network to achieve the following objectives:

- Prevent cars from blocking the intersection;
- Prioritize pedestrian movement above all else, given that the pedestrian movement is allowed for that phase;
- Force cars (and trucks) making a permitted left turn to check for clearances in all of: opposite direction through traffic, crossing pedestrians, and downstream lane availability; and
- Force cars (and trucks) making a permitted right turn to check for crossing pedestrians and downstream lane availability.
- For $12^{\text {th }}$ Avenue at City Square Plaza, cars always yield to freely crossing pedestrians.

Right Turn on Red (RTOR) was permitted for all right-turning movements on the following intersections: $11^{\text {th }}$ Avenue $\&$ Albert Street, $12^{\text {th }}$ Avenue \& Albert Street, $11^{\text {th }} \&$ Broad Street, $12^{\text {th }}$ Avenue \& Broad Street, $11^{\text {th }}$ Avenue \& Lorne Street, and $11^{\text {th }}$ Avenue \& Cornwall Street.

On-street parking was made available for select stretches along $11^{\text {th }}$ Avenue, $12^{\text {th }}$ Avenue, Albert Street, Broad Street, Smith Street, Lorne Street, and Hamilton Street.

For each alternative and time period, ten simulation runs of one simulated hour were completed to provide a statistical average. The simulation included a 15 minute seeding period, in which the network was populated with appropriate flow of vehicles. Data measurements were taken after the seeding period, for 60 minutes of simulation time, making the total simulation time 75 minutes per iteration. This approach ensured that the network was sufficiently loaded with vehicles prior to collecting measures of performance.

The VISSIM model is also capable of producing 3D videos of the simulation runs.

Exhibit 2-14: VISSIM 3D Model, at $11^{\text {th }}$ Avenue and Cornwall Street

### 2.4 Volume Balancing and Assignment

### 2.4.1 BASE MODEL

Due to the fact that approach volumes and turning movement counts were collected from different sources on different days, the following approach was taken to ensure that volumes were balanced across the network:

- All available vehicle volume data was tabulated together.
- Turning movement ratios were finalized for each intersection, based on given data. In cases where multiple resources were available for a single intersection, traffic movement counts (TMC) took precedent over turning movements from the reference Synchro files (from section 1.3.6).
- Where available, TMCs for intersection volumes were used as given for the appropriate hour. The peak hour was determined by picking the hour with the highest total volume, to 15 -minute accuracy scale.
- Approach volumes were multiplied by turning movement ratios for intersections without TMCs. Where neither TMC nor approach counts were available, the reference Synchro volumes were used.
- Between intersections, if there was a volume discrepancy between upstream and downstream volume, and a parking lot and/or parkade was available in the link, the difference in volume was balanced by adding/subtracting appropriate number of vehicles to/from the parking lots and parkades.
- Between intersections, if there was a volume discrepancy between upstream and downstream volume, and there weren't any parking lots or parkades available in the link, information based on observations and intuition was used to determine a suitable reference volume, then both the upstream and downstream volumes were adjusted accordingly. For most cases, the lower volume was bumped up to match the higher volume.

It was found that for all locations, approach counts yielded higher volumes than TMCs. Volumes were then balanced across the network, using the TMC as lower-bound cap. At few locations, balanced volumes resulted in higher approach totals than those from approach counts.

### 2.4.2 ALTERNATIVE MODELS

Re-balancing network volumes for the four alternative models were based on EMME and VISSIM model results. For the full list of reference volumes and simulated volumes, refer to Appendix B-3.

- From EMME, the link volume differentials for each of the alternatives compared to the base model was calculated for all links within the phase 1 boundary.
- Due to the use of centroids (not real vehicle sources such as parking lots, parkades, etc.), the EMME adjustments did not result in a balanced network.
- For the portion of the volume that entered or exited centroids that are in the phase 1 boundary, the trip differential percentages compared to the base case was noted, then distributed accordingly to the connected links.
- Results from specific select-link analysis in EMME was used to determine turning movement ratios and paths for newly added trips. Similar, the same analysis results were useful in determining the number of trips to be subtracted from the appropriate intersections.
- After EMME-related adjustments, similar balancing approach from section 2.4.1 above was taken to balance volumes between upstream and downstream intersections.
- The balanced volume was tested on the corresponding VISSIM network (i.e. one-way eastbound volumes on one-way eastbound network) for detection of any major new problems or issues.
- If the simulated volumes in VISSIM for any of the movements were off by more than $25 \%$ of the target reference volumes, the reference volumes were edited and balanced with the same approach from section 2.4 .1 above. Then, appropriate changes to VISSIM routing decisions were made, then the entire network was re-simulated.
- The above were repeated in multiple iterations until all of the following criteria were met:
o Non-minor movements (with turning movement volume of at least 60) were within $+/-$ $20 \%$ of the target reference volumes;
o Major movements (with turning movement volume of at least 300 ) were within $+/-15 \%$ of the target reference volumes; and
o The total simulated turning movement count for the entire network was within $2.5 \%$ of the total reference turning movement count.
- All buses were accounted for in the volume balancing process.

## 3. AUTO OPERATIONS

Intersection capacity analyses were undertaken using the Highway Capacity Manual (HCM) methodology. The level of service (LOS) and corresponding delay per vehicle is provided in the following tables:

Signalized Intersection LOS

| LOS | Control Delay Per Vehicle |
| :---: | :--- |
| A | $\leq 10$ |
| B | $>10$ and $\leq 20$ |
| C | $>20$ and $\leq 35$ |
| D | $>35$ and $\leq 55$ |
| E | $>55$ and $\leq 80$ |
| F | $>80$ |

Unsignalized Intersection LOS

| LOS | Control Delay Per Vehicle |
| :---: | :--- |
| A | $\leq 10$ |
| B | $>10$ and $\leq 15$ |
| C | $>15$ and $\leq 25$ |
| D | $>25$ and $\leq 35$ |
| E | $>35$ and $\leq 50$ |
| F | $>50$ |

Exhibit 3-1: Overall Model Results

| VISSIM Models - Traffic Results | Total Network Delay (hrs) | Difference from Base/Closed (hrs) | \% Difference |
| :--- | :---: | :---: | :---: |
| Base (Closed) | 160.0 | n/a | n/a |
| 1-Way Eastbound | 152.7 | -7.3 | $-5 \%$ |
| 1-Way Westbound | 140.7 | -19.3 | $-13 \%$ |
| 2-Way | 137.8 | -22.2 | $-14 \%$ |
| 1-Way Westbound, Preferred | 143.9 | -16.1 | $-10 \%$ |
| 1-Way Westbound Preferred Improved | 142.1 | -17.9 | $-12 \%$ |

On average, all five models operate smoothly, with majority of intersection turning movements operating at LOS A, B, or C. With the average delay under 20 seconds and queues no longer than 5 cars long, the averages for all the models suggest that in general, the Regina downtown road network is functioning well. There are few turning movements that operate at LOS D or worse, and they are discussed in section 3.3.

### 3.1 Intersection Operations

For each signalized and unsignalized intersections on $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue, intersection average delay was collected in both Synchro and VISSIM.

Exhibit 3-2: Intersection Operations, Base Model

| 12th Avenue | Albert Street | D | C | 35 | 23 |
|  | Mcintyre Street | B | A | 12 | 9 |
|  | Smith Street | B | B | 12 | 15 |
|  | Lorne Street | C | B | 21 | 18 |
|  | Cornwall Street |  |  |  |  |
|  | Scarth Street | A | A | 10 | 7 |
|  | Hamilton Street | B | B | 13 | 14 |
|  | Rose Street | B | B | 16 | 14 |
|  | Broad Street | C | B | 22 | 20 |

With the exception of the two intersections on Albert Street, the Synchro results and VISSIM results agree with each other. On $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue in between Albert Street and Broad Street, the intersections operate in LOS C or better. Generally, $11^{\text {th }}$ Avenue is heavier than $12^{\text {th }}$ Avenue in volume, and the intersection operations reflect that; intersections on $11^{\text {th }}$ Avenue have slightly higher delays than their counterparts on $12^{\text {th }}$ Avenue.

The two intersections on Albert Street show a major discrepancy between Synchro (LOS C or D) and VISSIM (LOS B or C). The average delays between Synchro and VISSIM range from 12 seconds to 22 seconds, depending on the alternative. In particular, Synchro calculates the southbound and northbound movements on Albert Street to experience major delays (LOS E), but in VISSIM the corresponding movements were found to operate with no major delays (LOS B or C).

Despite the overall network averages in the range of LOS B and intersection average in the range of LOS A to D, there are several movements that suffer from major delays. Movements that exit the phase 1 boundary at Albert Street and Broad Street suffer LOS D or E. For example, at the intersection of $11^{\text {th }}$ Avenue and Broad Street, the eastbound through movement and eastbound left movement share a single lane. The total volume from the two movements are considerably large for a single lane to process (240-320 depending on the alternative). Additionally, due to the left turning movement being restricted to permitted (not protected) turns only, the clearance of the lane is highly dependent on the volume of opposing direction through movement (WBT). Lane reconfiguration to separate the two movements, via methods such as adding a storage lane for the left turns only, is recommended for these intersections.

The full list of delays, broken down into individual movements at every intersection, can be found in Appendix B-4.

Exhibit 3-7: Intersection Operations Comparisons

| East-West Street | North-South Street | VISSIM Delays |  |  |  |  |  |

|  | Broad Street | 20 | 19 | 19 | 19 | 20 | 24 |

Exhibit 3-8: Comparison of Intersection Delays on $11^{\text {th }}$ Avenue

Exhibit 3-9: Comparison of Intersection Delays on $12^{\text {th }}$ Avenue

Overall, between the five alternatives, the intersection delays are within reasonable ranges of each other. On $11^{\text {th }}$ Avenue, one-way eastbound option results in greater delays than even the base option. One-way westbound option and two-way option result in similar sized delay reductions, but do not result in significant reductions compared to the base model. One-way westbound preferred option falls somewhere in between the one-way westbound option and the base case.

On $12^{\text {th }}$ Avenue, delays stay very similar between the five alternatives. The delays on intersections of $12^{\text {th }}$ Avenue with Lorne Street, Cornwall Street, and Scarth Street are highly dependent on the road configurations of the alternative, and it is sometimes not available due to the intersection not being existent in particular alternatives.

### 3.2 Critical Movements

There were several critical movements identified in the base model. Movements with LOS D or worse were identified in the base model and the alternatives models, and compared against their corresponding counterparts in the other models.

Exhibit 3-10: Critical Intersection Turning Movements

| Location |  |  |  | Delay |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| East-West Street | North-South Street | Movement | Base | 1WayEB | 1WayWB | 2Way | 1WayWBPref | 1WBPImp |  |
| 11th Avenue | Cornwall Street | NBL | 67 | 45 | 37 | 29 | 40 | 33 |  |
|  |  | NBR | 59 | 38 | 31 | 25 | 32 | 29 |  |
| 11th Avenue | Hamilton Street | SBR | 70 | 72 | 13 | 12 | 24 | 25 |  |
| 11th Avenue | Rose Street | WBT | 42 | 46 | 14 | 13 | 23 | 13 |  |
| 11th Avenue | Broad Street | EBL | 83 | 70 | 76 | 67 | 75 | 36 |  |
|  |  | EBT | 77 | 64 | 69 | 62 | 69 | 33 |  |
|  |  | WBL | 61 | 56 | 52 | 53 | 54 | 43 |  |
|  |  | WBT | 60 | 57 | 50 | 51 | 52 | 38 |  |
| 12th Avenue | Albert Street | EBL | 49 | 48 | 51 | 51 | 53 | 56 |  |
|  |  | WBL | 69 | 63 | 76 | 85 | 79 | 79 |  |
|  |  | WBT | 64 | 58 | 74 | 84 | 74 | 76 |  |
| 12th Avenue | Broad Street | SBL | 58 | 47 | 44 | 44 | 48 | 31 |  |

- On $11^{\text {th }}$ Avenue and Cornwall Street, the northbound left movement is no longer critical in the alternatives with $11^{\text {th }}$ Avenue westbound traffic reduced.
- On $11^{\text {th }}$ Avenue and Hamilton Street, the southbound right movement experiences enormous improvement in the alternatives with $11^{\text {th }}$ Avenue westbound traffic reduced.
- On $11^{\text {th }}$ Avenue and Rose Street, the westbound through movement is critical for the oneway eastbound option. The changes in vehicle routing and volumes generally result in higher delays westbound for the entire one-way eastbound option.
- On $11^{\text {th }}$ Avenue and Broad Street, the critical movements are not completely relieved in any of the alternatives. High volumes in all directions and select movements operating well over capacity are some of the factors contributing to the poor service at this location.
- Similar problems are found in $12^{\text {th }}$ Avenue and Albert Street, where critical movements are not completely relieved in any of the alternatives. Some movements improve and others degrade for all alternatives.
- On $12^{\text {th }}$ Avenue and Broad Street, the southbound left movement experiences high delays for all alternatives, largely unaffected by any of the volume, path, or operational changes in the alternatives.
- The one-way westbound preferred-improved model features significant improvement on some of the previously critical locations, such $11^{\text {th }}$ Avenue \& Broad Street and $12^{\text {th }}$ Avenue \& Broad Street. While according to Exhibit 3-7 the overall intersection delay increased in this model, the select critical movements were improved as a result of the changes to signal timing plan and lane configurations. More details regarding the improvements are available in Section 6.

### 3.3 Individual Vehicle Delays

In VISSIM, it is possible to extract the total delay incurred by a single vehicle through its journey in the network. This delay includes delay at signals, delays due to queues, and other 'obstacles' such as pedestrians or dwelling buses. This delay does not include the time spent parking in a designated parking spot. The sampled vehicles have all completed their trip, each from an entry point to an exit point in the network.

A sample of $\sim 2500$ vehicles were extracted from each of the models and grouped into bins of 30 , then graphed.

Exhibit 3-11: 30-Second Bin Counts, Vehicle Trip Total Delay

| Base |  | 1WayEB |  | 1WayWB |  | 2Way |  | 1WayWBPref |  | 1WBPImp |  |

| 330 | 19 | 330 | 12 | 330 | 5 | 330 | 5 | 330 | 9 | 330 | 4 |
| 360 | 9 | 360 | 7 | 360 | 2 | 360 | 1 | 360 | 8 | 360 | 3 |
| 390 | 12 | 390 | 8 | 390 | 3 | 390 | 1 | 390 | 6 | 390 | 1 |
| 420 | 3 | 420 | 10 | 420 | 2 | 420 | 0 | 420 | 1 | 420 | 0 |
| 450 | 8 | 450 | 3 | 450 | 1 | 450 | 0 | 450 | 1 | 450 | 1 |
| 480 | 6 | 480 | 4 | 480 | 1 | 480 | 0 | 480 | 0 | 480 | 0 |
| 510 | 4 | 510 | 1 | 510 | 0 | 510 | 0 | 510 | 0 | 510 | 0 |
| 540 | 3 | 540 | 3 | 540 | 0 | 540 | 0 | 540 | 0 | 540 | 0 |
| 570 | 0 | 570 | 1 | 570 | 0 | 570 | 0 | 570 | 0 | 570 | 0 |
| 600 | 3 | 600 | 1 | 600 | 0 | 600 | 0 | 600 | 0 | 600 | 0 |

Exhibit 3-12: Vehicle Trip Total Delay

From Exhibit 3-12, the one-way eastbound alternative peaks the highest at around 50 seconds, then falls off quickly like the other alternatives. The higher peak at the low delay range means that higher portion of the vehicles experienced delays within that range. In other words, the higher peak relates to more vehicles experiencing relatively low total delay. The one-way eastbound alternative is a close winner in this analysis: compared to other options, it has about 30-50 more cars in the low delay range. All models follow a similar curve, indicating that the overall traffic pattern will be similar between no matter the option.

Exhibit 3-13: Cumulative Percentages for Vehicle Trip Total Delay

In the cumulative percentages graph, two-way and one-way westbound preferred-improved options have the "highest" curves, reaching higher percentage of vehicles under certain delay time thresholds, and reaching the 100\% at the fastest pace. Base model has the "lowest" curve, and it does not reach completion until the 450 s mark. This means that the base model potentially has the most vehicles in the high delay range, and all other alternatives will have less vehicles in the high delay range.

### 3.4 Auto Travel Times

To calculate the total travel time between two observation points, appropriate travel time measurements from individual segments are added together.

Exhibit 3-15: $11^{\text {th }}$ Avenue Total Eastbound and Westbound Travel Times

In the eastbound direction, all five options result in similar travel times. The changes in volume and vehicle paths that come with the different options have very little affect in travel time. From the base ( 226 seconds) to the one-way eastbound model ( 204 seconds), the improvement is less than $10 \%$. Major travel time improvement is achieved by the one-way westbound preferred-improved model: at the intersection of $11^{\text {th }}$ Avenue and Broad Street, an eastbound left turn storage lane is added, accompanied by a new eastbound left protected phase. This reduces the eastbound delays at that intersection by about $50 \%$, resulting in major travel time savings.

In the westbound direction, the differences in travel time is more apparent. The one-way eastbound alternative results in higher travel time westbound than the base model. The one-way eastbound is aimed at improving the conditions eastbound, and there are no major changes in the road configuration that warrant a penalty to the westbound traffic. The increase of travel time in the oneway eastbound option is focused in the east end of $11^{\text {th }}$ Avenue within the phase 1 boundary (at intersections with Hamilton Street, Rose Street, and Broad Street), which suggest that the change in vehicle volumes and paths result in higher levels of congestion at those intersections.

All models with the exception of base and one-way eastbound involve reduction of volume in the $11^{\text {th }}$ Avenue westbound direction. As a result, the previously congested corridor is relieved to varying degrees, and westbound travel times are improved accordingly.

Exhibit 3-16: $12^{\text {th }}$ Avenue Travel Times, All Models

| 12th Avenue |  | Closed | 1WayEB | 1WayWB | 2Way | 1WayWBPref | 1WBPImp |

| Broad Street | Rose Street | 16 | 16 | 16 | 16 | 16 | 16 |
| Rose Street | Hamilton Street | 21 | 10 | 23 | 24 | 27 | 25 |
| Hamilton Street | Scarth Street | n/a | n/a | 9 | 9 | 10 | 10 |
| Scarth Street | Cornwall Street | n/a | n/a | 22 | 22 | 22 | 21 |
| Cornwall Street | Lorne Street | n/a | n/a | 30 | 31 | 29 | 28 |
| Lorne Street | Smith Street | 25 | 20 | 22 | 22 | 20 | 21 |
| Smith Street | Mcintyre Street | 10 | 10 | 12 | 12 | 12 | 12 |
| Mcintyre Street | Albert Street | 72 | 65 | 82 | 82 | 83 | 85 |

Due to some of the options not having continuous roads between Lorne Street and Hamilton Street, a full end-to-end travel time was not calculated on $12^{\text {th }}$ Avenue. Instead, on an individual segment basis, all five options experience similar travel times between each other. Against corresponding segments on $11^{\text {th }}$ Avenue, the segments in $12^{\text {th }}$ Avenue experience similar travel times as well.

On both $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue, the segments leading up to Albert Street or Broad Street experience significant congestion. Heavy volumes and insufficient intersection capacity at those locations are the main factors that contribute to high travel times.

### 3.5 Individual Travel Times

In VISSIM, it is possible to extract the travel time of a single vehicle through its journey in the network. This travel time is the difference between the end trip time of the vehicle and the start trip time of the vehicle. This travel time does not include the time spent parking in a designated parking spot. The sampled vehicles have all completed their trip, each from an entry point to an exit point in the network.

Exhibit 3-18: Vehicle Trip Travel Time

Similar to the delays, the graph peaks at a low range then falls off towards the end. Surprisingly, the base option peaks at similar heights as three of the four options, indicating that there is no significant improvement from the base to most of the alternatives. One-way eastbound peaks the highest, suggesting that there are large number of cars taking short, relatively delay-free trips in that particular option. However, all other models peak at similar range and retain similar graph curve, which means that the travel time differences are most likely very small between the models.

Exhibit 3-19: Cumulative Percentages for Vehicle Trip Travel Time

Similar to Exhibit 3-13, Exhibit 3-19 has all five options in a similar trend. All options are virtually equal: 60-70\% of all trips are completed within 2 minutes ( 120 seconds), and only $5-8 \%$ trips take longer than 5 minutes. As it was noted in the EMME analysis, the small percentage of $5+$ minute trips are likely those of the vehicles using $11^{\text {th }}$ Avenue or $12^{\text {th }}$ Avenue as a through corridor, from one end of the model to the other.

## 4. TRANSIT OPERATIONS

The existing transit operations are based on the base model, which represents the PM peak hour with $12^{\text {th }}$ Avenue closed between Lorne Street and Scarth Street. Transit routes were modelled only for the VISSIM model - detailed transit modelling is not possible in EMME and Synchro. Due to the fact that all Regina public transit routes do not use $12^{\text {th }}$ Avenue between Lorne Street and Hamilton Street, all bus routes are identical between the five options.

### 4.1 Transit Routes in the VISSIM Model

The full list of bus lines and schedules were obtained from the transit section of City of Regina official website, at http://regina.ca/residents/transit-services/regina-transit. All listed routes, from 1 Dieppe - Broad North to 23 - University - Rochdale, were included in the model if any portion of their route is present inside or on the phase 1 boundary. Any transit lines that do not have any portion of their route present inside or on the phase 1 boundary were not included in the model.

TransitLive is an automatic vehicle location pilot project from Canadian Research Logistics (CRL), a Regina-based company. In addition to the schedules obtained from City of Regina's official website, TransitLive was used to verify routes and stop locations. TransitLive is accessible to the public, and can be found online at http://transitlive.com.

Exhibit 4-1: TransitLive, Showing Route 1 Stops and Buses

For the purposes of bus schedules and arrival times,

- The AM model was assumed to run from 6:45 AM to 8:00 AM;
- The off-peak model was assumed to run from 12:45 PM to 2:00 PM; and
- The PM peak model was assumed to run from 3:45 PM to 5:00 PM.

Bus dwell times at bus stations were given static distributions, and thus do not vary by passenger occupancy, boarding, or alighting volumes. Dwell time distributions range from short (normal, 15 +/5 seconds) to long (empirical, 30 to 240 seconds), depending on the observed significance of the stop.

All bus routes were modelled individually. Bus routes start and end where they cross the VISSIM model boundary (different from phase 1 boundary). The routes do not share a common time and headway. The individual routes' starting times were coordinated to best match the first scheduled departure time at the City Hall stop within the model's time frame. For routes that do not use the City Hall stop, the nearest station was used as the point of reference.

Bus-only routes were modelled at appropriate segments along $11^{\text {th }}$ Avenue and $12^{\text {th }}$ Avenue. Lane violations by automobiles were modelled as well: at $11^{\text {th }}$ Avenue and Scarth Street, a small static chance was coded into the routing decisions to have westbound automobiles make a short stop (dwell time is based on a static normal distribution), which disrupt and/or delay the buses trying to make a stop or pass through.

For major stops used by several bus lines (such as the City Hall eastbound stop or the Cornwall Plaza westbound stop), bus stops were elongated to accommodate for up to 4 buses to dwell simultaneously. In the case for Cornwall Plaza westbound stop, the stop was split into nearside and farside stops - each with capacity for 3 buses to dwell simultaneously - and the bus lines that use the stop were assigned to either one of the stops according to the information from TransitLive.

### 4.2 Intersection Level of Service - for Transit Vehicles

Select segments were modelled as bus-only routes in the model. This was accomplished either by placing restrictions the outside lane of a 2-lane link for vehicles, or modelling the road as two separate 1-lane links.

Exhibit 4-2: Overall Model Results, for Transit-Only Movements

| VISSIM Models - Transit Results | Average Delay (s) | Level of Service | Average Queue (m) |
| :--- | :---: | :---: | :---: |
| Base (Closed) | 20 | B | 12 |
| 1-Way Eastbound | 21 | C | 11 |
| 1-Way Westbound | 18 | B | 8 |
| 2-Way | 18 | B | 8 |
| 1-Way Westbound, Preferred | 20 | B | 10 |
| 1-Way Westbound, Preferred, Improved | 19 | B | 8 |

The delays on transit-only movements are similar to those of mixed traffic. With delays less than 30 seconds, buses are usually able to proceed through the intersection within one signal cycle.

### 4.3 Transit Travel Times

The travel time measurement segments for buses start at the downstream end of a bus stop and end at the upstream end of a bus stop. This ensures that dwell times at bus stops have no effect on the travel times. Unlike regular traffic, bus travel times are measured from stop to stop, and total travel time between selected points is calculated by the sum of appropriate stop-to-stop times.

Exhibit 4-3: Transit Travel Time for Selected Routes

| Transit Routes |  | Closed | 1WayEB | 1WayWB | 2Way | 1WayWBPref | 1WBPImp |

| 11th \& Broad | 11th \& Broad | 560 | 532 | 521 | 505 | 529 | 492 |

Exhibit 4-4: Bus Route A, Westbound, from $11^{\text {th }}$ Avenue \& Broad Street to City Hall

Exhibit 4-5: Bus Route B, Southbound, from $11^{\text {th }}$ Avenue \& Albert Street to City Hall

Exhibit 4-6: Bus Route C, Eastbound, from City Hall to 11th Avenue \& Broad Street

Exhibit 4-7: Bus Route, D, Loop, from and to $11^{\text {th }}$ Avenue \& Broad Street

Exhibit 4-8: Transit Travel Times for Selected Routes

Bus travel times are somewhat longer than auto travel times, despite having the advantage of the bus-only lanes on most of $11^{\text {th }}$ Avenue between Albert Street and Broad Street. Routes that require the bus to take an eastbound left turn at $11^{\text {th }}$ Avenue and Broad Street incur large travel times due to the fact that the particular movement suffers a LOS E ( $\sim 80$ s delay). The exception is the one-way westbound preferredimproved option, where that same movement only suffers a LOS D ( $\sim 36 \mathrm{~s}$ delay).

Between the alternatives, bus travel time does not differ by a significant margin. Based on the longest route measured - the loop around downtown - the two-way option has a 9\% travel time improvement compared to the base conditions. Imposing further network improvements with on the preferred design did improve the bus travel times by 27-43 seconds, but only for the routes that use the eastbound left turn at $11^{\text {th }}$ Avenue and Broad Street.

The intended vehicle disruptions at $11^{\text {th }}$ Avenue and Scarth Street, as well as several patches of illegal roadside parking, all contribute to slower travel times for buses.

Additionally, due to the bus schedules, bus arrivals tend to be in large clumps, rather than spread out evenly throughout the simulation hour. Although the chances of it happening is low, buses arriving in large packs consisting of 4 buses or more can cause minor queuing at smaller bus stops.

## 5. PEDESTRIAN AND CYCLIST OPERATIONS

### 5.1 Pedestrians

Pedestrian crossings were implemented on every leg of all signalized intersections. Pedestrian crossings were also implemented at the two unsignalized intersections on McIntyre Street, but not for the parkade entrances.

Pedestrian volumes, walking speeds, and crossing locations are identical between all alternatives.

### 5.2 Cyclists

Cycle paths were not modelled.
Isolated network tests were done on a stand-alone replica of the $12^{\text {th }}$ Avenue at City Square Plaza. Bike lanes parallel to the $12^{\text {th }}$ Avenue traffic made no impact on the adjacent traffic. Bike path crossings across $12^{\text {th }}$ Avenue achieved essentially the same effect as the pedestrian crossings; when necessary, traffic came to a stop at a safe distance to allow cyclists across. Since the model only incorporates a finite number of crossing paths across $12^{\text {th }}$ Avenue at City Square Plaza, and because it was possible to include cyclists in the same paths as pedestrians, explicit cycle paths were not modelled.

All pedestrian movements across the network consist of $94 \%$ pedestrian and $6 \%$ bicycle composition, a ratio based on the received City of Regina counts.

### 5.3 Operations and Conflicts

All modelled pedestrian crossings were observed to operate with no major problems. Although total pedestrian volumes were not measured in the model, all observed pedestrians and cyclists cleared the crossings within the appropriate green phases.

Due to pedestrians being given the highest priority within their green phase, no pedestrian delays or problems were observed during the simulation. Vehicles making permitted right turns yielded to pedestrians, and vehicles looking to make permitted left turns waited until sufficient space was cleared in the pedestrian link before making the turn. From the opposing perspective, high pedestrian volumes did not allow the cars to make the left turn despite having no opposite direction through-movement vehicle traffic.

At some intersections, the queue spillback and vehicle blockages resulted in vehicles being stuck fully or partially on pedestrian crossings. As an unintended bi-product of the various priorities set in the network, pedestrians walk straight across and through the blocking vehicles if they have the signal right-of-way. Additionally, once the upstream clears up, those blocking vehicles sometimes proceed through the intersection despite not having the signal right-of-way. In real life, the blocking cars would remain in place until the next green signal with all conflicting pedestrians and vehicles clear, and pedestrians would walk around the blocking vehicles (it is physically impossible to walk through a vehicle).

## 6. NETWORK IMPROVEMENTS

Following model development and evaluations, critical movements were identified in both Synchro and VISSIM models. For selected few of these movements, the recommended improvements were incorporated into the preferred (one-way westbound preferred) model.

- $\quad 11^{\text {th }}$ Avenue at Hamilton Street: westbound left turns in this intersection was found to be blocking the heavy volume of westbound through movements, since they share the same lane. There was no provision of protected phase for the left turn, making it difficult for vehicles to find a sufficient safe gap in the opposing through traffic in order to make the turn. Additionally, the left turning cars yielded to pedestrians, yet another challenge added to the already difficult turn. Thus, the left turn was removed entirely - to be prohibited via signage and enforcement. This left turn should be prohibited in correspondence with the transit lane hours.
- $11^{\text {th }}$ Avenue at Broad Street: eastbound movements were experiencing heavy delays (LOS E or F) for several reasons, such as high volume, limited number of lanes, and lack of protected phasing for left turns. Similar to the case of $11^{\text {th }}$ Avenue at Hamilton Street, left turning vehicles were waiting a long time to find a safe gap, while all the through-movement vehicles had to wait in the same line. In the new signal timing plan, the cycle (120s) is maintained, but a new eastbound left turn protected phase is introduced to relieve the queue more effectively.
- $12^{\text {th }}$ Avenue at Broad Street: the problem is similar with $11^{\text {th }}$ Avenue at Broad Street. Likewise, an EBL protected phase is introduced to the signal timing plan. Additionally, a right turn bay is added for westbound approach.

As a result, delays for the aforementioned movements were reduced significantly. In particular, for $11^{\text {th }}$ Avenue at Broad Street, the EBL and EBT delays were each reduced by about $50 \%$. In the larger picture, this improvement also benefits the bus routes that use those movements.

Overall, the network delay between one-way westbound preferred model and the one-way westbound preferred-improved model are the very similar. The traffic diverted from $11^{\text {th }}$ Avenue at Hamilton Street WBL are distributed to Broad Street southbound, Cornwall Street southbound, and Smith Street southbound, adding some delay to those streets. Changes in signal timing plans that benefit targeted movements also degraded other movements of the same intersection, resulting in a net gain or loss of near zero for the intersection operations.

For transit operations, the eastbound improvement for $11^{\text {th }}$ Avenue at Broad Street is critical. The savings in delay translate directly to savings in travel time. As shown in Exhibit 4-8, the bus travel time improves noticeably for routes that use the eastbound left movement.

## 7. CONCLUSIONS

Upon the completion of the development and validation of the existing conditions (base) model, three main alternatives were developed: one-way eastbound, one-way westbound, and two-way, each named for the operational scheme of $12^{\text {th }}$ Avenue at City Square Plaza. Additionally, after studies and discussions about streetscape and public safety, the fourth alternative was developed, based on the one-way westbound model, but with additional limitations on traffic movements. Each alternative was modelled in three different modelling platforms: EMME, Synchro, and VISSIM, with the exception of one-way westbound preferred alternative which did not need an EMME model.

Overall, all four alternatives and the base model were found to be operating at LOS B. Individual intersections were found to be operating at LOS A to LOS D, with few individual movements being at overcapacity and LOS E. Although all the models were experiencing low delays on average, some movements still require attention and improvements.

Individual vehicle delay and travel time analyses yielded trends suggesting that the two-way model provided the best operations, but only by a slight margin. All alternatives and the base model performed at similar levels. Majority of vehicles were found to complete their trips within 5 minutes.

Transit travel times were found to be slightly higher than their auto equivalents on the same routes, for the base model and the four alternatives. llegal car movements were found to be creating minor blockages on bus lanes. All transit routes use at least one turning movement that is shared with cars, and is operating at LOS D or E. Due to the size and speed differences, buses need wider safe gaps for left turns and thus have a harder time compared to cars.

Pedestrians and cyclists were modelled at pedestrian crossings all analyzed intersections within the phase 1 boundary, and also at the City Square Plaza. Those two modes shared the same crossings, and were given highest priority in potential conflict zones with cars and buses. Based on visual observations, modelled pedestrians and cyclists did not experience any delays or crashes (other than the signal delay at signalized intersections).

Network improvements were found to benefit select transit routes, but did not provide a significant reduction in delay or travel time for majority of the vehicles in the network.

## APPENDIX B-3

VISSIM OUTPUT - INTERSECTION OPERATIONS

| Node \# | Intersection |
| :---: | :--- |
| 101 | 11th Avenue \& Albert Street |
| 102 | 11th Avenue \& Mcintyre Street |
| 103 | 11th Avenue \& Smith Street |
| 104 | 11th Avenue \& Lorne Street |
| 105 | 11th Avenue \& Cornwall Street |
| 106 | 11th Avenue \& Scarth Street |
| 107 | 11th Avenue \& Hamilton Street |
| 108 | 11th Avenue \& Rose Street |
| 109 | 11th Avenue \& Broad Street |
| 201 | 12th Avenue \& Albert Street |
| 202 | 12th Avenue \& Mcintyre Street |
| 203 | 12th Avenue \& Smith Street |
| 204 | 12th Avenue \& Lorne Street |
| 205 | 12th Avenue \& Cornwall Street |
| 206 | 12th Avenue \& Scarth Street |
| 207 | 12th Avenue \& Hamilton Street |
| 208 | 12th Avenue \& Rose Street |
| 209 | 12th Avenue \& Broad Street |
| 801 | Parkade on Cornwall Street |
| 802 | Parkade on Rose Street |
| 901 | City Square Plaza west of Cornwall Street |
| 902 | City Square Plaza east of Cornwall Street |
